Abstract

We prove that recent data demonstrates unequivocally that the scalar meson $f_0(980)$ is mostly composed of $s\bar{s}$ quarks and that the coupling of f_0 to photons and mesons is in agreement with expectations from the linear sigma model.

PACS: 13.20.Gd, 13.25.+m, 14.40.Cs

The observation[1] of the decay mode $\phi(1020) \rightarrow \pi^0\pi^0\gamma$ was reported very recently for the first time. The experiment clearly shows that the process is dominated by the $f_0(980)\gamma$ channel. This may be contrasted with the decay process $J/\psi \rightarrow \omega\pi\pi$, which was measured a decade ago[2] and where it was found that the $\omega f_0(980)$ channel was highly suppressed but that the $\omega\sigma(500)$ and $\omega f_2(1270)$ channels predominated. In this letter we wish to give an interpretation of these results and show that the $f_0(980)$ scalar meson is mostly composed of strange quarks.

First we recall that, according to quark models, the vector meson $\omega(782)$ is 97% nonstrange (viz. $NS=(u\bar{u} + d\bar{d})/\sqrt{2}$) and 3% strange ($S=s\bar{s}$). Conversely, the other vector meson $\phi(1020)$ has the opposite composition: 3%

*Permanent address: Physics Department, University of Arizona, Tucson, Az. 85721 USA.

NS and 97% S. We will show that the above two experiments[1, 2] strongly suggest that the $f_0(980)$ is largely S. Independently and for different reasons the phenomenological study of low-energy $\pi\pi$ scattering[3] and the phase shift analysis[4] of πK scattering have led to the same conclusion about the composition of $f_0(980)$.

The effective coupling constants, extracted from ref. [1], are based upon an inferred f_0 total decay width of 188^{+48}_{-33} MeV:

$$g_{f_0\pi^+\pi^-}^2/4\pi = 0.51^{+0.13}_{-0.09} \text{ GeV}^2 \quad \text{or} \quad |g_{f_0\pi^+\pi^-}^{eff}| \simeq 2.5 \pm 0.3 \text{ GeV}, \quad (1)$$

$$g_{f_0K^+K^-}^2/4\pi = 2.10^{+0.88}_{-0.56} \text{ GeV}^2 \quad \text{or} \quad |g_{f_0K^+K^-}^{eff}| \simeq 5.1 \pm 0.9 \text{ GeV}. \quad (2)$$

These values roughly follow from a dynamically generated theory of the SU(3) linear sigma model ($L\sigma M$) Lagrangian[5] where a scalar meson nonet pattern is demanded: $\sigma_{NS}(670), \kappa(810), \sigma_S(940), a_0(984)$. A related description[6] is that the scalar mesons are composed of 4 quarks ($qq\bar{q}\bar{q}$), which is the description adopted by ref. [1].

In order to bring the observed[7] isoscalar mesons $\sigma(600)$ and $f_0(980)$ into the $L\sigma M$ picture, we must first consider the NS-S mixing basis,

$$|\sigma\rangle = \cos\phi_s|\sigma_{NS}\rangle - \sin\phi_s|\sigma_S\rangle, \quad |f_0\rangle = \sin\phi_s|\sigma_{NS}\rangle + \cos\phi_s|\sigma_S\rangle \quad (3)$$

in a manner similar to $\eta - \eta'$ mixing[8]. For the orthogonal mixed states $\langle\sigma|f_0\rangle = 0$, we find[5] from (3),

$$m_{\sigma_{NS}}^2 = m_\sigma^2 \cos^2\phi_s + m_{f_0}^2 \sin^2\phi_s, \quad m_{\sigma_S}^2 = m_\sigma^2 \sin^2\phi_s + m_{f_0}^2 \cos^2\phi_s. \quad (4)$$

Inserting the dynamically generated NJL-type masses[5],

$$m_{\sigma_{NS}} = 2\hat{m} \simeq 670 \text{ MeV}, \quad m_{\sigma_S} = 2m_s \simeq 940 \text{ MeV}, \quad (5)$$

along with $m_{f_0} \simeq 980$ MeV, one gets

$$m_\sigma = [m_{\sigma_{NS}}^2 + m_{\sigma_S}^2 - m_{f_0}^2]^{1/2} \simeq 610 \text{ MeV}, \quad \phi_s = \arcsin \left[\frac{m_{f_0}^2 - m_{\sigma_{NS}}^2}{m_{f_0}^2 - m_\sigma^2} \right]^{1/2} \simeq 20^\circ. \quad (6)$$

Such a value for the scalar mixing angle was proposed several years ago[8] and it is worth noting that the proximity in mass between $\sigma_S(940)$ and $f_0(980)$

has its counterpart in the vector mesons with $\phi_S(985)$ and $\phi(1020)$. Thus one should not be surprised that the $f_0(980)$ meson (with $\cos 20^\circ \simeq 0.94$) is principally an $s\bar{s}$ state.

In order to link up to the recently extracted interactions (1) and (2), we first state the predicted L σ M Lagrangian couplings[5] (for brevity we refer to either the $\pi^+\pi^-$ or K^+K^- final states as $\pi\pi$ or KK),

$$\begin{aligned} g_{\pi\sigma_{NS}\pi} &= (m_{\sigma_{NS}}^2 - m_\pi^2)/2f_\pi \simeq 2.3 \text{ GeV}, \\ g_{K\sigma_{NS}K} &= (m_{\sigma_{NS}}^2 - m_K^2)/4f_K \simeq 0.45 \text{ GeV}, \\ g_{K\sigma_SK} &= (m_{\sigma_S}^2 - m_K^2)/2\sqrt{2}f_K \simeq 2.1 \text{ GeV}, \end{aligned} \quad (7)$$

where we have substituted the experimental values $f_\pi \simeq 93 \text{ MeV}$, $f_K/f_\pi \simeq 1.22$. From these and the mixing angle $\phi_s \simeq 20^\circ$ we may compute the effective[9] L σ M couplings,

$$g_{f_0\pi\pi}^{eff} = 2 \sin \phi_s g_{\pi\sigma_{NS}\pi} \simeq 1.6 \text{ GeV}, \quad (8)$$

$$g_{f_0KK}^{eff} = 2 \sin \phi_s g_{K\sigma_{NS}K} + 2 \cos \phi_s g_{K\sigma_SK} \simeq 4.3 \text{ GeV}. \quad (9)$$

Although these predictions (8) and (9) seem shy of (1) and (2) by 64% and 84% respectively, we have not yet considered other data.

Specifically, the detailed Particle Data Group (PDG) Tables[7] quote the average decay rate $f_0 \rightarrow \gamma\gamma$ to be $0.56 \pm 0.11 \text{ keV}$. In combination with the $f_0 \rightarrow \gamma\gamma$ branching ratio[7] of $(1.19 \pm 0.33) \times 10^{-5}$, one may derive a total f_0 width of $47 \pm 16 \text{ MeV}$. Given the $f_0 \rightarrow \pi\pi$ branching ratio, one may deduce the PDG effective coupling[9],

$$|g_{f_0\pi\pi}^{eff}|_{PDG} = 1.1 \pm 0.4 \text{ GeV}. \quad (10)$$

($|g_{f_0KK}|_{PDG}$ is unknown, because of the negligible phase space.)

This said, we note that our theoretical values (8) and (9) lie between the Novosibirsk and PDG values. See Table 1. Regardless of the final phenomenological resolution of the discrepancy, we must emphasize that the important result is the contrast between the measured $\pi\pi$ invariant mass spectra of refs. [1] and [2].

	New Data	L σ M Theory	Particle Data Group
$g_{f_0\pi\pi}^{eff}$	2.5 ± 0.3	1.6	1.1 ± 0.4
$g_{f_0KK}^{eff}$	5.1 ± 0.9	4.3	-

Table 1: Comparison of effective couplings (in GeV) of f_0 to the pseudoscalar mesons.

For the reader's convenience, we display the observed invariant $\pi^0\pi^0$ mass spectrum in $\phi \rightarrow \pi^0\pi^0\gamma$ in Figure 1; our quark model interpretation is given alongside, in Figure 2. The observed $\pi\pi$ mass spectra for $J/\psi \rightarrow \omega\pi\pi$ are displayed in Figure 3 to show the stark difference from Figure 1; again we provide the quark model interpretation alongside, in Figure 4. The resonance bumps $f_0(980)$ in $\phi \rightarrow \pi^0\pi^0\gamma$ and $\sigma(500)$ in $J/\psi \rightarrow \omega\pi\pi$ along with the near absence of an $f_0(980)$ bump in $J/\psi \rightarrow \omega\pi\pi$ and of $\sigma(500)$ in $\phi \rightarrow \pi^0\pi^0\gamma$ is telling us that $\sigma(500)$ is mostly NS while f_0 is mainly S. This is in consonance with the linear sigma model and a scalar mixing angle of $\phi_s \sim 20^\circ$.

However, to stress that this small mixing angle of ϕ_s is not the central issue, we close this letter by considering $f_0 \rightarrow 2\gamma$ decays which proceed via a quark loop. We may compare this radiative channel with $\pi^0 \rightarrow \gamma\gamma$, which is accurately estimated by a nonstrange quark triangle; the latter provides the effective amplitude $\alpha N_c/3\pi f_\pi \simeq 0.025 \text{ GeV}^{-1}$ and agrees with the data to within 2% for $N_c = 3$, $f_\pi \simeq 93 \text{ MeV}$.

If f_0 were purely nonstrange too, the (isoscalar) $f_0\gamma\gamma$ effective amplitude would be given by

$$|M(f_{0NS} \rightarrow 2\gamma)| = 5\alpha N_c/9\pi f_\pi \simeq 0.042 \text{ GeV}^{-1}, \quad (11)$$

predicting a decay rate

$$\Gamma(f_{0NS} \rightarrow 2\gamma) = m_{f_0}^3 |M_{NS}|^2/64\pi \sim 8 \text{ keV}. \quad (12)$$

On the other hand, if f_0 were a pure $s\bar{s}$ scalar, its effective $\gamma\gamma$ amplitude would be

$$|M(f_{0S} \rightarrow 2\gamma)| = \alpha N_c g_{f_0ss}/9\pi m_s \sim 0.0081 \text{ GeV}^{-1}, \quad (13)$$

for a constituent mass $m_s \simeq 490 \text{ MeV}$ and a strange f_0ss coupling[5] of $\sqrt{2}g_{\pi^0 qq} = \sqrt{2}2\pi/\sqrt{3}$. The decay rate would then be

$$\Gamma(f_{0S} \rightarrow 2\gamma) = m_{f_0}^3 |M_S|^2/64\pi \sim 0.3 \text{ keV}. \quad (14)$$

From (12) we see that the pure $f_{0NS} \rightarrow \gamma\gamma$ decay rate is about 15 times larger than the PDG[7] average rate of 0.56 keV, while the pure $f_{0S} \rightarrow \gamma\gamma$ rate (14) is within striking range of the experimental value. The comparison can be improved by including the small mixing angle ϕ_s . But in any case the quark triangle description of radiative meson decays reinforces the fact that $f_0(980)$ is mostly $s\bar{s}$ rather than a $(u\bar{u} + d\bar{d})$ scalar meson.

- [9] Effective couplings are defined via $\Gamma_{f_0\pi\pi} = 3p|g_{f_0\pi\pi}^{eff}|^2/16\pi m_{f_0}^2$ and they yield $g_{f_0\pi\pi}^{eff} \simeq 1.12$ GeV for $\Gamma_{f_0\pi\pi} = 0.781 \times 47$ MeV. We need to double the Lagrangian couplings by a factor of two to compare them with g^{eff} .
